1 Introduction

This is the report of the determination of the Limit of Quantitation (LoQ) for FVIII_Low_-Test assay with lot N001 in the ModTOP platform. The report has been automatically generated. Data analysis has been executed by Joey. The LoQ study was performed following the approved guideline CLSI EP17-A2 Evaluation of Detection Capability for Clinical Laboratory Measurement Procedures, 2nd Edition.

A Functional Sensitivity approach determined the LoQ. This approach characterizes the precision profile in the lower end of the measuring interval and defines the LoQ as the lowest measurand concentration that achieves a desired within-laboratory precision or precision goal. The experiment tested 11 low level samples for 5 days, 1 runs per day and 10 replicates per run.

1.1 Study Specifications and Acceptance Criteria

LoQ has acceptance criteria and specification. LoQ results were acceptable if they met the acceptance criteria shown in Table 1.

Table 1. LoQ Specification and Acceptance Criteria

Specification (activity)	Acceptance Criteria (precision goal as %CV)
≤1.00	20.00

Abbreviations: CV, Coefficient of Variation.

2 Materials and Equipment Description

The materials and equipment used in the present LoQ study are described in the corresponding section of DRC-248-01.

3 Exploratory Data Analysis

The exploratory data analysis helps to have a first impression about the data.

Table 2. Low Level Samples Exploratory Data Analysis Summary for lot N001.

Sample	N	Min (activity)	Max (activity)
DP	50	0.00	0.20
A	50	0.30	0.80
B	50	0.50	1.10
C	50	0.70	1.40
D	50	1.10	1.90
E	50	1.30	2.20
F	50	1.90	2.80
G	50	2.20	3.00
H	50	2.60	3.40
I	50	3.00	4.50
J	50	3.60	4.70

Abbreviations: N, Sample Size; Min, Minimum; Max, Maximum.

4 Results

Functional Sensitivity approach characterized the precision profile of the low level samples data to determine the LoQ as the lowest measurand concentration that achieves a within-laboratory precision goal.

4.1 Within-Laboratory Precision Profile

A Variance Components Analysis (VCA) determined the within-laboratory precision for each sample via restricted maximum likelihood (REML). This method is robust to balanced and unbalanced study designs since the final data set might be unbalanced due to missing values or excluded results as statistical outliers.

Table 3 contains the VCA results summary with the mean, the sample size (N), the within-laboratory standard deviation and the within-laboratory coefficient of variation for low level samples data.

Table 3. Within-laboratory precision for low level samples for lot N001.

Sample	N	Mean (activity)	SD_{WL} (activity)	CV_{WL} (%)
DP	50	0.13	0.06	47.59
A	50	0.52	0.13	25.82
B	50	0.82	0.12	14.04
C	50	1.12	0.15	13.07
D	50	1.42	0.18	12.41
E	50	1.88	0.21	10.92
F	50	2.32	0.20	8.59
G	50	2.59	0.17	6.60
H	50	3.05	0.20	6.60
I	50	3.82	0.30	7.85
J	50	4.13	0.24	5.88

Abbreviations: N, Sample Size; SD_{WL}, Within-Laboratory Standard Deviation; CV_{WL}, Within-Laboratory Coefficient of Variation.

4.2 LoQ Results for Simple Linear Regression with Variables Transformations

This analysis fitted simple linear regression to the precision profile of within-laboratory coefficient of variation (CV_{WL}) versus mean concentration of low level samples (Figure 1), assessing multiple transformations of both variables.

Table 4 summarizes the assessed linear transformations with their equations, model parameters, goodness of fit parameters of root mean squared error (RMSE) and coefficient of determination (R^2) and the estimated LoQ as the mean concentration at the CV_{WL} goal, sorted from lowest to greatest RMSE. Estimated LoQ at CV_{WL} goal (last column, Table 4) as N/A indicates a negative estimated LoQ or that the LoQ cannot be estimated. Figure 1 shows the fitted line of the lowest RMSE model along with its estimated LoQ.

R^2 utilizes the transformed Y scale (CV_{WL}), while RMSE the original Y scale. Selecting among models with different transformations of Y makes the RMSE the most meaningful goodness of fit parameter. The lower RMSE, the better fitting.

The linear precision profile model with the lowest RMSE interpolated a LoQ of 0.58 activity.

Table 4. List of the models for multiple linear transformations for lot N001

Equation	Transformation	β_0	β_1	R^2	RMSE	LoQ at CV_{WL} goal (activity)
$CV_{WL} = \beta_0 Mean^{\beta_1}$	$log(CV_{WL}), log(Mean)$	2.665	-0.6029	0.958	1.847	0.58
$CV_{WL} = \beta_0 + \beta_1/Mean$	$1/Mean$	7.304	5.32	0.936	2.986	0.42
$CV_{WL} = \beta_0 + \beta_1 \cdot log(Mean)$	$log(Mean)$	18.49	-11.43	0.913	3.462	0.88
$CV_{WL} = \beta_0 + \beta_1 Mean^{1/2}$	$Mean^{1/2}$	40.8	-20	0.727	6.140	1.08
$CV_{WL} = exp(\beta_0 + \beta_1 Mean)$	$log(CV_{WL})$	3.284	-0.4186	0.765	7.230	0.69
$CV_{WL} = (\beta_0 + \beta_1 Mean)^2$	$CV_{WL}^{1/2}$	5.204	-0.8148	0.658	7.386	0.90
$CV_{WL} = \beta_0 + \beta_1 Mean$	None	28.08	-6.854	0.544	7.940	1.18
$CV_{WL} = \beta_0 + \beta_1 Mean^2$	$Mean^2$	21.15	-1.203	0.330	9.624	0.98

Abbreviations: N/A, Not Applicable; R², Coefficient of Determination; RMSE, Root Mean Squared Error; CV, Coefficient of Variation; WL, Within-Laboratory precision.

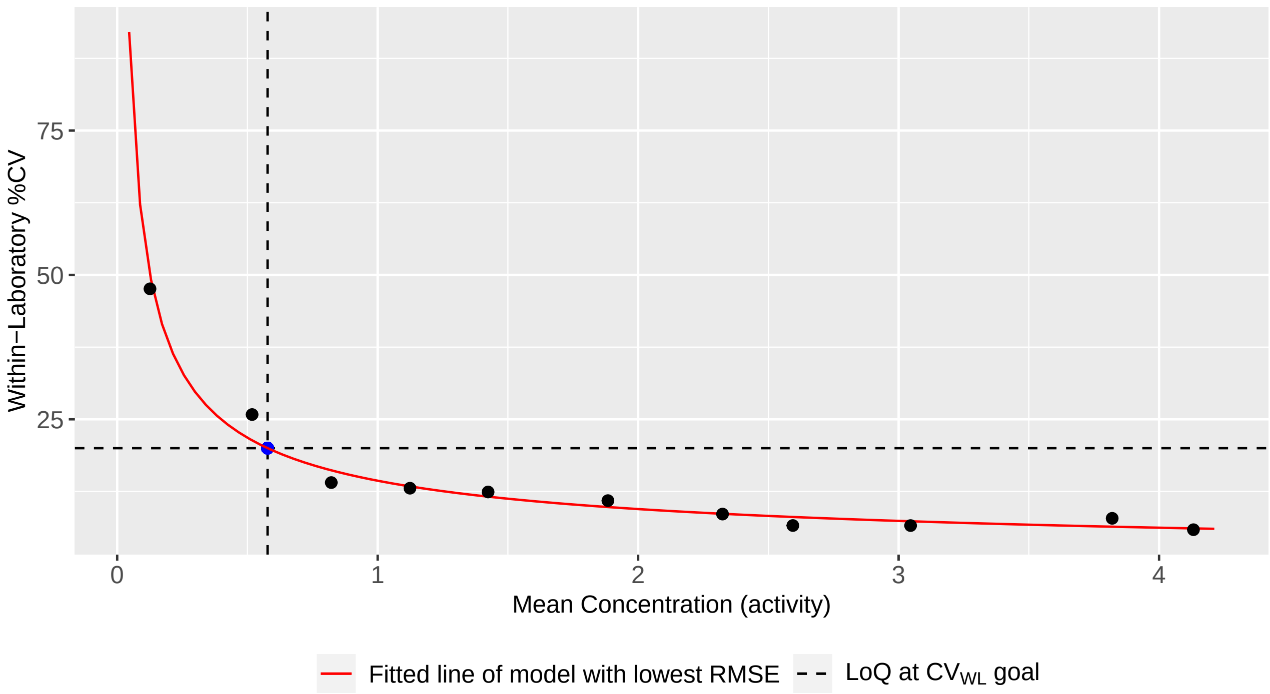

Figure 1. Precision profile plot with fitted linear regression model with lowest RMSE for lot N001.

4.3 LoQ Results for non-linear models

This analysis fitted multiple non-linear models to the precision profile of within-laboratory variance (SD^2_{WL}) versus mean concentration of the low level samples. SD^2_{WL} used for fitting the models was transformed into CV_{WL} for plotting the precision profile (Figure 2). These models are variance functions commonly applied in clinical literature.

Table 5 summarizes the evaluated models with their equations, model parameters, Akaike Information Criterion (AIC) and estimated LoQ as the mean concentration at the CV_{WL} goal, sorted from lowest to greatest AIC. Estimated LoQ at CV_{WL} goal (last column, Table 5) as N/A indicates a negative estimated LoQ, that the LoQ cannot be estimated or that the model connot be estimated (e.g., due to convergence errors or an insuficient number of low level samples). Figure 2 shows the fitted line of the lowest AIC model along with its estimated LoQ.

The multiple fitted models had different numbers of parameters. The proposed model was selected using AIC instead of RMSE since AIC accounts not only for the goodness of fit, but also for model complexity, favoring simpler models with fewer parameters. The lower the AIC, the better, where negative numbers are allowed.

The non-linear precision profile model with the lowest AIC interpolated a LoQ of 0.59 activity.

Table 5. List of the non-linear models fitted to the precision profile for lot N001.

Equation	$\boldsymbol{\beta_1}$	$\boldsymbol{\beta_2}$	$\boldsymbol{\beta_3}$	**J**	**AIC**	**LoQ at CV_{WL} goal (activity)**
$SD^2_{WL} = \beta_1 \cdot Mean^J$	0.02111	N/A	N/A	0.8057	-1709.006	0.59
$SD^2_{WL} = \beta_1 + \beta_2 \cdot Mean^J$	9.867e-39	0.02111	N/A	0.8057	-1709.006	0.59
$SD^2_{WL} = (\beta_1 + \beta_2 \cdot Mean)^J$	4.297e-17	0.008329	N/A	0.8057	-1709.006	0.59
$SD^2_{WL} = (\beta_1 + \beta_2 \cdot Mean)^2$	0.07847	0.05174	N/A	N/A	-1540.495	0.53
$SD^2_{WL} = \beta_1 + \beta_2 \cdot Mean^2$	0.01109	0.004823	N/A	N/A	-1435.399	0.56
$SD^2_{WL} = \beta_1$	0.03546	N/A	N/A	N/A	-1167.802	0.94
$SD^2_{WL} = \beta_1 + \beta_2 \cdot Mean + \beta_3 \cdot Mean^J$	0.01826	-5.323e+14	5.323e+14	1	-974.228	22.36*

Abbreviations: N/A, Not Applicable; AIC, Akaike Information Criterion; CV, Coefficient of Variation; WL, Within-Laboratory precision.

*Model extrapolated the LoQ value.

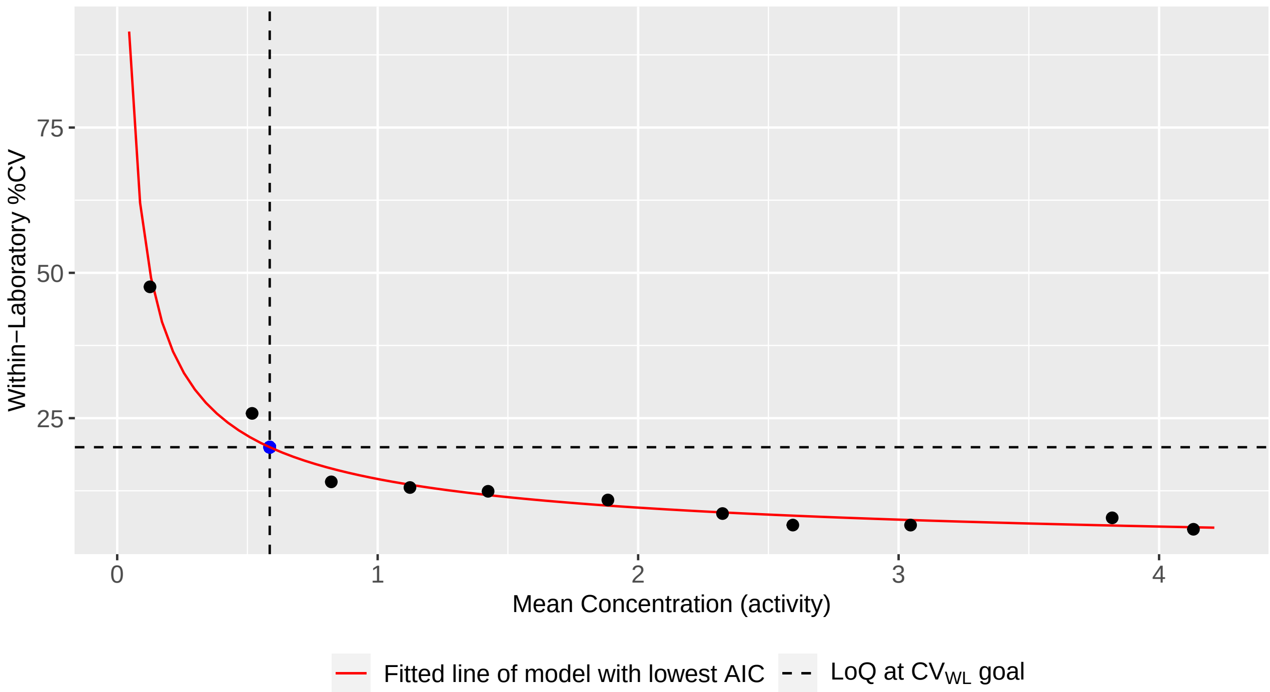

Figure 2. Precision profile plot with fitted non-linear model with lowest AIC for lot N001.

4.4 Results Summary

Claiming a LoQ using a precision profile model depends on selecting an appropriate fit, either by linear or non-linear regression. Visual inspection (Figures 1 and 2) and summary statistics (Tables 4 and 5) help justify model choice. A good model has data points evenly distributed around the fitting line, while gaps or patterns in the data can distort results. When RMSE or AIC values are similar, choose the simpler model with fewer parameters. For linear regression, an R^2 much lower than 0.9–1 indicates poor fit.

4.4.1 Simple linear regression with variables transformations

The linear precision profile model with lowest RMSE interpolated a LoQ of 0.58 activity. If the fitting looks good, the estimated LoQ might be claimed as the assay's LoQ. If the fitting does not look good, it is not recommended to claim the interpolated LoQ as the assay's LoQ. Revisit Table 4 in case other fitted models interpolated the LoQ while keeping a good fitting.

Alternatively, sort low-level sample results from lowest to highest and select the lowest result that meets the precision goal, ensuring all higher results also satisfy this goal. As a worst-case scenario, select the highest low-level sample result that meets the precision goal.

4.4.2 Non-linear models

The non-linear precision profile model with lowest AIC interpolated a LoQ of 0.59 activity. If the fitting looks good, the estimated LoQ might be claimed as the assay's LoQ. If the fitting does not look good, it is not recommended to claim the interpolated LoQ as the assay's LoQ. Revisit Table 5 in case other fitted models interpolated the LoQ while keeping a good fitting.

Alternatively, sort low-level sample results from lowest to highest and select the lowest result that meets the precision goal, ensuring all higher results also satisfy this goal. As a worst-case scenario, select the highest low-level sample result that meets the precision goal.
